Passage A
 The Search for Extraterrestrial Intelligence (SETI) is still no trivial task. Our galaxy is 100,000 light-years across and contains a hundred thousand million stars. Searching the entire sky for some faraway and faint signal is an exhausting exercise.

Some simplifying assumptions are useful to reduce the size of the task. One is to assume that the vast majority of life-forms in our galaxy are based on carbon chemistries, as are all life-forms on Earth. While it is possible that life could be based around atoms other than carbon, carbon is well-known for the unusually wide variety of molecules that can be formed around it. The presence of liquid water is also a useful assumption, as water is a common molecule and provides an excellent environment for the formation of complicated carbon-based molecules that could eventually lead to the emergence of life. A third assumption is to focus on Sun-like stars. Very big stars have relatively short lifetimes, meaning that intelligent life would not likely have time to evolve on planets orbiting them. Very small stars provide so little heat and warmth that only planets in very close orbits around them would not be frozen solid, and in such close orbits these planets would be tidally "locked" to the star, with one side of the planet perpetually baked and the other perpetually frozen.
